

and what functionalities are allowed to be accessed by users. This also allows us to understand the flaw in the system and upgrade accordingly or make a modification to the existing systems.

5. Prototyping

Prototyping is another technique used for dealing with the scenarios when there is uncertainty about the requirements. A model is built about the system based on the information collected and this is called prototyping. The users can give feedback on the prototype made and modifications are done until user requirements are met. During this process the users might give new requirements and change the existing ones. Sometimes a user is not exactly aware of the features that is to be implemented in the system. Prototyping may allow users to be aware of it and finally develop a better product. The prototyping method provide two kinds of requirements:

1.Product level requirements: In this level, prototyping defines the functionalities that is realistic and useful.

2.Design level requirements: In this level, prototyping defines the statistics for goals of the system.

Prototyping has some advantages and disadvantages in the development of software.

Helps developer reduce the development time as feedback can significantly speed up the process. Prototyping increases the interaction between people and developers and contributes in building a good software the brings user satisfaction.

However, this technique might lead to incomplete documentations.

These are the requirements elicitation techniques used in software engineering.
