

What Is Requirements Elicitation?

The first activities that tries to define the project scope and elicit user requirements. It is all about obtaining information from stakeholders. In other words, once the business analysis has communicated with stakeholders to understand their requirements, it can be described as elicitation. It can also be described as a requirement gathering. Requirement elicitation can be done by communicating with stakeholders directly or by doing some research, or experiments. The activities can be planned, unplanned, or both.

Requirements Elicitation Techniques

Direct Approach: In direct approach the purpose is to enhance the understanding of the problems of system that is currently in used. Most common techniques used are Interviews, case study, Prototyping.

Indirect Approach: Indirect methods are used in order to obtain information that cannot be easily articulated directly. Questioners, documents analysis are its examples.

There are several techniques available for elicitation, however, the commonly used techniques are explained below:

Interview

This is the most common technique used for requirement elicitation. Interview techniques should be used to build strong relationships between business analysts and stakeholders. In this technique, the interviewer directs the question to stakeholders to obtain information. The one-to-one interview is the most commonly used technique.

If the interviewer has a predefined set of questions then it's called a structured interview.

If the interviewer is not having any particular format or any specific questions then it's called an unstructured interview.

Prototyping

Prototyping is used to identify missing or unspecified requirements. In this technique, frequent demos are given to the client by creating prototypes so that the client can get an idea of how the product will look like. Prototypes can be used to create a mock-up of sites and describe the process using diagrams.

Questionnaire

Surveys and Questionnaires help Analysts gather data about common challenges faced by end users, such as issues with similar products or prototypes. These tools are used to explore complex or frequent problems customers experience.

Software Development relies on feedback from all involved parties. Expert Analysts create Surveys and Questionnaires for online data collection during the elicitation process. Validation of the software often comes through user acceptance, which surveys help define.

Observation

Observation, or job shadowing, allows Analysts to see objectives and ideas first-hand. Analysts use this method to gather examples of business processes, regulations, and key clients by shadowing staff to identify new requirements and preferences.

Observation is especially useful at the start of a project. It helps Analysts prepare resources, structure tasks, and gather focused input. The main benefits include first-hand understanding and early identification of potential risks.

Document Analysis

Document analysis of similar software can uncover specifications that may have been missed during other elicitation methods. Analysts review existing documentation to find relevant requirements for the new software being developed. Studying existing software and documents helps identify missed features and tools during the software development process. This method ensures more complete and accurate requirements, working behind the scenes to avoid gaps.
